## Chapter 2

# CHU'S CONSTRUCTION: A PROOF-THEORETIC APPROACH 

Gianluigi Bellin*<br>Facoltà di Scienze<br>Università di Verona<br>bellin@sci.univr.it

#### Abstract

The essential interaction between classical and intuitionistic features in the system of linear logic is best described in the language of category theory. Given a symmetric monoidal closed category $\mathcal{C}$ with products, the category $\mathcal{C} \times \mathcal{C}^{o p}$ can be given the structure of a $*$-autonomous category by a special case of the Chu construction. The main result of the paper is to show that the intuitionistic translations induced by Girard's trips determine the functor from the free *-autonomous category $\mathcal{A}$ on a set of atoms $\left\{P, P^{\prime}, \ldots\right\}$ to $\mathcal{C} \times \mathcal{C}^{o p}$, where $\mathcal{C}$ is the free monoidal closed category with products and coproducts on the set of atoms $\left\{P_{O}, P_{I}, P_{O}^{\prime}, P_{I}^{\prime}, \ldots\right\}$ (a pair $P_{O}, P_{I}$ in $\mathcal{C}$ for each atom $P$ of $\mathcal{A}$ ).

Keywords: Chu spaces, proof-nets, linear logic

## 1. Preface

An essential aim of linear logic [16] is the study of the dynamics of proofs, essentially normalization (cut elimination), in a system enjoying the good prooftheoretic properties of intuitionistic logic, but where the dualities of classical logic hold. Indeed classical linear logic CLL has a denotational semantics and a game-theoretic semantics; proofs are formalized in a sequent calculus, but also in a system of proof-nets and in the latter representation cut elimination not only has the strong normalizability property, but is also confluent. Although Girard's main system of linear logic is classical, considerable attention in the literature has also been given to the system of intuitionistic linear logic

[^0]ILL, where proofs are also formalized in a sequent calculus and in a natural deduction system. A better understanding of the relations between CLL and ILL is one of the goals to which the present work is intended as a contribution.

The fact that intuitionistic logic plays an important role in the architecture of linear logic is not surprising: as indicated in the introductory section of Girard's fundamental paper [16], a main source of inspiration for the system was its denotational semantics of coherent spaces, a refinement of Scott's semantics for the $\lambda$-calculus. Fundamental decisions about the system CLL were made so that CLL has a semantics of proofs in coherent spaces in the same way as intuitionistic logic has a semantics of proofs in Scott's domains. But linear logic is not just a refinement of intuitionistic logic, such as ILL: there are expectations that CLL may tell us something fundamental about classical logic as well, indeed, that through linear logic a deep level of analysis may have been reached from which the "unity of logic" can be appreciated [17]. Therefore the relations between classical and intuitionistic components of linear logic deserve careful investigation.

A natural points of view to look at this issue is categorical logic. It has been known for years that monoidal closed categories provide a model for intuitionistic linear logic, though a fully adequate formulation of the syntax and of the categorical semantics of ILL especially with respect to the exponentials, has required considerable subtlety and effort $[4,5,6]$. It is also well known that $*$-autonomous categories give a model for classical linear logic [3]. The appendix to [2] provides a method, due to Barr's student Chu, to construct *-autonomous categories starting from monoidal closed ones.

In our proof-theoretic investigation we encounter a special case of Chu's construction, namely $\operatorname{Chu}(\mathcal{C}, T)$ where $\mathcal{C}$ is a symmetric monoidal closed category with terminal object $T$. More specifically, given the free $*$-autonomous category $\mathcal{A}$ on a set of objects (propositional variables) $\left\{P, P^{\prime}, \ldots\right\}$ and given the symmetric monoidal closed category $\mathcal{C}$ with products, free on the set $\left\{P_{O}\right.$, $\left.P_{I}, P_{O}^{\prime}, P_{I}^{\prime}, \ldots\right\}$ (a pair $P_{O}, P_{I}$ in $\mathcal{C}$ for each atom $P$ of $\mathcal{A}$, the category $\mathcal{C} \times \mathcal{C}^{o p}$ can be given the structure of a $*$-autonomous category by Chu's construction. Indeed, since the dualizing object is the terminal object, $\mathbf{C h u}(\mathcal{C}, T)$ is just $\mathcal{C} \times \mathcal{C}^{o p}$ and the pullback needed to internalize the homsets is in fact a product. Here the tensor product $\left(X, X^{o p}\right) \otimes\left(Y, Y^{o p}\right)$ must be an object of the form $\left(X \otimes Y,\left(X \multimap Y^{o p}\right) \times\left(Y \multimap X^{o p}\right)\right)$ and the identity of the tensor must be (1, $\top$ ). Dually, the $\operatorname{par}\left(X, X^{o p}\right) \wp\left(Y, Y^{o p}\right)$ is defined as $\left(\left(X^{o p} \multimap\right.\right.$ $\left.Y) \times\left(Y^{o p} \multimap X\right), X^{o p} \otimes Y^{o p}\right)$ and the identity of the par must be $(\top, \mathbf{1})$. Now since $\mathcal{A}$ is free, there is a functor $F$ of $*$-autonomous categories from $\mathcal{A}$ to $\left(\mathcal{C} \times \mathcal{C}^{o p}\right)$ taking $P$ to $\left(P_{O}, P_{I}\right)$. This is well-known, but so far no familiar construction had been shown to correspond to the functor $F$ given by the abstract theory. The main contribution of this paper is to show that a familiar
proof-theoretic construction, namely Girard's trips [16] on a proof-net, represent the action of such a functor on the morphisms of $\mathcal{A}$. Of course one could state the same result using Danos-Regnier graphs, as it was done in [8], but as we shall see a simpler definition of orientations is possible in terms of Girard's trips.

The key idea is simple enough and may be illustrated as a logical translation of formulas and proofs in CMALL into formulas and proofs in IMALL. In the translation a CMALL sequent $S: \vdash \Gamma, A$ becomes polarized: a selected formula-occurrence $A$ is mapped to a positive formula-occurrence $A_{O}$ in the succedent of an intuitionistic sequent $S^{\prime}$ (the output part of a logical computation); all other formula-occurrences $C$ in $\Gamma$ are mapped to negative $C_{I}$ in the antecedent of $S^{\prime}$ (the input part). The polarized occurrences of an atom $A$ become $A_{O}, A_{I}$, just two copies of $A$. Negation changes the polarity. For other complex polarized formulas, the polarization of the immediate subformulas is uniquely determined - for instance, $\left(A_{\wp} B\right)_{I}$ becomes $A_{I} \otimes B_{I}$ - except in the cases of $(A \wp B)_{O}$ and $(A \otimes B)_{I}$. In these cases we take the product (logically, the with) of two possible choices (the "switches" in a proof-net): for instance, $(A \wp B)_{O}$ is encoded as $\left(A_{I} \multimap B_{O}\right) \&\left(B_{I} \multimap A_{O}\right)$. The intuitive motivation is clear: $A \wp B$ has a reading simultaneously as the internalization of the function space $\operatorname{Hom}_{\mathcal{A}}\left(A^{\perp}, B\right)$ and of the function space $\operatorname{Hom}_{\mathcal{A}}\left(B^{\perp}, A\right)$. The fact that the translation is functorial here means, roughly, that it is defined independently on the formulas (objects) and on the proofs (morphisms) and that it admits the rule of Cut (composition of morphisms); it is also compatible with cut-elimination. In this form the result can be easily proved within the formalisms of the sequent calculi for CMALL and IMALL. However, when we ask questions about the faithfulness and fullness of such a functor, thus also asking questions about the identity of proofs in linear logic, we find it convenient to consider the more refined syntax of proof-nets.

On the other hand, proof-nets are also useful to highlight the geometric aspect of certain logical properties; indeed ideas related to the present result have already proved quite useful in the study of what is sometimes called the géometrie du calcul (geometry of computations). Our own investigation has been motivated by the desire to understand and clarify the notion of a proof-net and the present result appears to reward many collective efforts in this direction. Given a proof-structure, i.e., a directed graph where edges are labeled with formulas, a correctness criterion characterizes those proofstructures which correspond to proofs in the sequent calculus. Girard's original condition ("there are no short trips") [16] is exponential in time on the size of the proof-structure, but other quadratic criteria were found soon after (among others, one was given in [7]). Thus it is natural to ask what additional information is contained in the construction of Girard's trips other than the correctness
of a proof-structure. The beginning of an answer came in 1992, when Jacques van de Wiele and the author, inspired by Danes' notion of a pure net, defined the trip translation: every Girard's trip on a cut-free proof-net corresponds to a derivation in the fragment of intuitionistic linear logic with times and linear implication. But the significance of this result seemed limited by the fact that the treatment of cut was quite cumbersome and the result itself did not seem to extend beyond the multiplicative fragment. A better understanding of its significance - and, as we hope, the possibility of its generalization - has come only from an explicit effort to formulate the trip translation as a functorial operation. In this way it became evident that classical multiplicative linear logic has to be related to intuitionistic multiplicative and additive linear logic and the categorical result followed, for which we gratefully acknowledge the influence and the support of Martin Hyland.

There is a conspicuous literature on Chu's spaces and linear logic. Moreover Chu's construction is related to many other more concrete semantics that yield full completeness results for fragments of linear logic, from R. Loader's Linear logical Predicates [22] to various game-theoretic semantics (cf. [26]). Clearly this is not the place to survey such a body of literature. It is impossible however not to mention the work of V. Pratt, who has advocated this direction of research for a long time (see, e.g., [25]) and has recently obtained (with Plotkin et al. [11]) a full completeness result for multiplicative linear logic (without units) with respect to Chu spaces. Chu's construction $\operatorname{Chu}(\mathcal{H}, \top)$ where $\mathcal{H}$ is a Heyting algebra, is also explicitly used by Anna Patterson in her thesis ([24], Section 6.7.), to show that the algebra of constructive duality is a model of CLL with Mix (we are grateful to an anonymous referee for this reference).

Among the researchers who have worked on proof-nets and developed ideas related to the trip translation, we should mention F. Lamarche, who introduced the notion of essential net for intuitionistic linear logic [20] in the context of his research on the game-theoretic semantics [21]. Arnaud Fleury has considered trips and intuitionistic translations in a non-commutative context with explicit exchange rule [13], giving one of the most interesting and least understood developments in this area. Already in 1992-93 the consideration of trips as translations from classical to intuitionistic linear logic had suggested the possibility of giving a linear time correctness condition for proof-nets: after all, just one unsuccessful trip suffices to discard a proof-structure as incorrect, and just one successful trip, if appropriately translated to an intuitionistic derivation, suffices to test the correctness of a proof-net. However only in 1999 Murawski and Ong [23] were able to prove such a conjecture, making essential use of a result of Gabow and Tarjan [15].

When the languages and the aims of different scientific communities meet in a new theory and new structures are identified, the conceptual architecture
may look different from the different points of view and it may be hard to say which structures are fundamental. From the point of view of categorical logic Chu's construction seems to suggest a fundamental status to monoidal closed categories with respect to the $*$-autonomous ones. However, such a view must accompanied by the warning that the correspondence established by our interpretation of Chu's construction is not an isomorphism, as the functor $F$ is not full, and its faithfulness at the moment is only a conjecture. Research towards a refinement of the present result, in particular with respect to the units and the additives is in progress, as well as towards its extension to the exponentials. Finally, further work is needed to spell out intriguing analogies between our version of Chu's construction and the game theoretic semantics of linear logic.

## 2. The trip translation

In this section, after the basic formal definitions we present our functorial translation from the sequent calculus for CMALL to that for IMALL , we state the categorical result and sketch the proof.

### 2.1 Languages, intuitionistic and classical MALL

The syntax of propositional classical Linear Logic CLL is given in Girard [16]: formulas are in "negation normal form", i.e., they are built from propositional constants $\mathbf{1}, \perp, \top$ and 0 , atoms $P_{i}$ and negations of atoms $\left(P_{i}\right)^{\perp}$ using the connectives $\otimes, \wp, \&$ and $\oplus$ and the exponential operators ! and ?; linear negation for nonatomic formulas is defined and linear implication is also defined, see in Table 0.

$$
\begin{array}{cccc}
\perp^{\perp}={ }_{d} \mathbf{1} & \mathbf{1}^{\perp}={ }_{d} \perp & (A \otimes B)^{\perp}={ }_{d} A^{\perp} \wp B^{\perp} & (A \wp B)^{\perp}={ }_{d} A^{\perp} \otimes B^{\perp} \\
\mathrm{T}^{\perp}==_{d} \mathbf{0} & \mathbf{0}^{\perp}={ }_{d} \top \quad(A \& B)^{\perp}={ }_{d} A^{\perp} \oplus B^{\perp} \quad(A \oplus B)^{\perp}={ }_{d} A^{\perp} \& B^{\perp} \\
& (!A)^{\perp}={ }_{d} ?\left(A^{\perp}\right) \quad(? A)^{\perp}={ }_{d}!\left(A^{\perp}\right) \\
A \multimap B==_{d} A^{\perp} \wp B
\end{array}
$$

Table 0: Definition of linear negation and linear implication.

CMALL [CMLL] is the fragment of CLL without exponentials [without exponentials and additives]; $\mathbf{C M L} \mathbf{L}^{-}$is $\mathbf{C M L L}$ without propositional constants.

Recall that the sequent calculus for propositional CMALL is defined by the axioms and rules given in Table 1:

| identity rules <br> logical axiom: <br> $\vdash A^{\perp}, A$ <br> $\stackrel{\vdash}{\vdash, A^{\text {cut: }}} \stackrel{\Delta}{\vdash}, A$ |  |  |  |
| :---: | :---: | :---: | :---: |
|  |  |  |  |
|  |  |  |  |
| structural rules exchange: |  |  |  |
| $\vdash \Gamma, A, B, \Delta$ |  |  |  |
| $\vdash \Gamma, B, A, \Delta$ |  |  |  |
| one: | nil: $\quad$ logical rules |  | par: |
| $\vdash 1$ | $\vdash \Gamma \quad \vdash \Gamma$, | $A \vdash \Delta, B$ | $\vdash \Gamma, A, B$ |
|  |  | $\Delta, A \otimes B$ | $\vdash \Gamma, A \wp B$ |
| true:$\stackrel{-}{ }+\top$ | with: | plus: | for $i=0,1$. |
|  | $\vdash \Gamma, A \vdash \Gamma, B$ | $\vdash \Gamma, A_{i}$ |  |
| $\vdash \Gamma, \top$ | $\vdash \Gamma, A \& B$ | $\vdash \Gamma, A_{0} \oplus A_{1}$ |  |

Table 1: The sequent calculus CMALL.

The propositional language of intuitionistic Linear Logic ILL is built from a set of propositional atoms $\left\{P_{O}, P_{I}, P_{O}^{\prime}, P_{I}^{\prime}, \ldots\right\}$, and the propositional constants $\mathbf{1}, \top$ and $\mathbf{0}$, using the connectives $\multimap$ (linear implication) and $\otimes, \&$ and $\oplus$ and the exponential !. (We take the point of view that there is no symbol " $\perp$ " for "multiplicative falsity" in ILL Thus $P_{O}$ and $P_{I}$ may be regarded as "positive and negative atoms", respectively). Again IMALL is the fragment of $\mathbf{I L L}$ without exponentials, etc.

The sequent calculus for propositional IMALL has the axioms and rules given in Table 2.

Table 2: The sequent calculus IMALL.
When a derivation $\boldsymbol{\pi}$ (in CMALL or IMALL) ends with a cut inference and the immediate subderivations are $\pi_{1}, \pi_{2}$, we use the notation $\left(\pi_{1} \mid \pi_{2}\right)$ for $\pi$.

### 2.2 The functorial trip translation for MALL

Definition 1 (Trip translation) (i) The trip translation maps formulas of CMALL to pair of formulas of IMALL: $A \mapsto\left(A_{O}, A_{I}\right)$. The formulas of CMALL are first polarized and then translated into IMALL formulas. To say that a formula $A$ is polarized is to say that it is regarded either as an output $A_{O}$ (positive polarization) or as an input $A_{I}$ (negativepolarization).
(ii) The trip translation maps polarized atoms $P_{O}, P_{I}$ to atomic formulas of IMALL (also denoted by $P_{O}, P_{I}$, respectively). For polarized constants and polarized complex formulas the trip translation is defined inductively according to the table in Table 3.
(iii) A pointed sequent $\vdash \Gamma, \mathbf{A}$ is a sequent with a selected formula occurrence, i.e., with a switch choosing one of its formulas. The chosen formula will be written in boldface.

Table 3: Functorial trip translation, the propositions.
(iv) The polarization of a sequent $\vdash \Gamma, \mathbf{A}$ is defined as follows: the selected formula $\mathbf{A}$ is regarded as an output $A_{O}$, all other formulas $C$ in $\Gamma$ are regarded as inputs $C_{I}$; we write $\Gamma_{I}$ to indicate this fact.
(v) The trip translation maps a pointed sequent $S=\vdash \Gamma, \mathbf{A}$ of CMALL to a sequent $S^{\prime}=\Gamma_{I} \vdash A_{O}$ of IMALL, where $\Gamma_{I}$ and $A_{O}$ are translated as in (ii). Notice that since a sequent $\vdash \Delta$ may be regarded as the par of all its formulas, by Table 3 the translation $\vdash(\wp(\Delta))_{O}$ of the pointed sequent $\vdash \wp(\boldsymbol{\Delta})$ is the product (with) of the translations of all the "pointings" of $\Delta$.
(vi) The trip translation maps sequent derivations of CMALL to sequent derivations in IMALL according to the definition in Table 4.
Proposition 2 For any formula A of CMALL, the translation satisfies $\left(A^{\perp}\right)_{O}$ $=A_{I}$ and $\left(A^{\perp}\right)_{I}=A_{O}$. Therefore the translation of the cut-rule is welldefined.

Proof. By induction on the logical complexity of $\mathbf{A}$.
Theorem 3 (i) The trip translation maps a CMALL proposition A to a pair of IMALL propositions $\left(A_{O}, A_{I}\right)$ and $a$ CMALL derivations $\pi$ of $\vdash \Gamma$ an IMALL derivation $\tilde{\pi}$ of $\vdash(\wp(\Gamma))_{O}$. If $\vdash \Gamma^{\prime}$, A is a pointing of $\vdash \Gamma$, then a branch of $\tilde{(\pi)}$ contains a derivation $\pi^{\prime}$ of $\Gamma_{I}^{\prime} \vdash A_{O}$.
(ii) The trip translation is functorial in the sense it preserves the cut rule. Namely, given a derivation $\left(\pi_{1} \mid \pi_{2}\right)$ ending with a cut

$$
\frac{\stackrel{\pi_{1}}{\Gamma}, A \quad \stackrel{\pi_{2}}{\vdash} \vdash A^{\perp}, \Delta}{\vdash \Gamma, \Delta}
$$

and a pointing $\vdash \Xi, \mathbf{C}$ of $\vdash \Gamma, \Delta$ there is a unique pair of pointings of $\vdash \Gamma, A$ and of $\vdash A^{\perp}, \Delta$ such that

$$
\left(\pi_{1} \mid \pi_{2}\right)^{\prime}=\left(\pi_{1}^{\prime} \mid \pi_{2}^{\prime}\right)
$$

(iii) Moreover, if $S$ is translated to $\mathbf{S}^{\prime}$ and $S$ reduces to $S_{0}$ by cut-elimination, then there exists $S_{0}^{\prime}$ which is the translation of $S_{0}$ and $S^{\prime}$ reduces to $S_{0}^{\prime}$.

|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 4: Functorial trip translation, the proofs.

Remark 4 (i) The concise notation of part (ii) of Theorem 3 can be spelt out as follows. Here $\left(\pi_{1} \mid \pi_{2}\right)^{\prime}$ is the trip translation of $\left(\pi_{1} \mid \pi_{2}\right)$ restricted to the given pointing $\vdash \Xi, \mathbf{C}$ of $\vdash \Gamma, \Delta$. Depending on whether $C$ is in $\Gamma$ or in $\Delta$ we have either the pair of pointings $\left\{\vdash A, \Gamma^{\prime}, \mathbf{C}, \vdash \Delta, \mathbf{A}^{\perp}\right\}$ or the pair $\left\{\vdash \Gamma, \mathbf{A}, \vdash A^{\perp}, \Delta^{\prime}, \mathbf{C}\right\}$. Moreover, $\pi_{1}^{\prime}$ and $\pi_{2}^{\prime}$ are the trip translations of $\pi_{1}$ and $\pi_{2}$ restricted to the appropriate pointings, i.e., either $\pi_{1}^{\prime}$ is a derivation of $A_{I}, \Gamma_{I}^{\prime} \vdash C_{O}$ and $\pi_{2}^{\prime}$ a derivation of $\Delta_{I} \vdash A_{I}$, or $\pi_{1}^{\prime}$ is a derivation of $\Gamma_{I} \vdash A_{O}$ and $\pi_{2}^{\prime}$ a derivation of $A_{O}, \Delta^{\prime} \vdash C$. The theorem says that $\left(\pi_{1} \mid \pi_{2}\right)^{\prime}$ is the same as the derivation $\left(\pi_{1}^{\prime} \mid \pi_{2}^{\prime}\right)$ which is obtained by applying cut to $\pi_{1}^{\prime}$ and $\pi_{2}^{\prime}$.
(ii) Notice that there is no anomaly in the $\perp_{O}$ rule. One pointing of $\vdash \Gamma, \perp$ selects $\perp$ and $\perp_{O}=\top$, thus one branch in the derivation $\tilde{\pi}$ of $\vdash(\wp(\Gamma, \perp))_{O}$ is given by the axiom $\Gamma_{I} \vdash \mathrm{~T}$. Such a branch adds no information in addition to that contained in the derivation of $\vdash(\wp(\Gamma))_{O}$ which is also contained in the other branches of $\tilde{\pi}$.

Fact 5 (i) To the trip translation there corresponds an obvious map in the opposite direction, let us write it as ( ) ${ }^{c}$; in proof-theoretic terms it amounts to regarding IMALL as afragment of CMALL, namely:

- writing formulas in "negation normal form", using De Morgan laws as in Table 0 and then rewriting $\left(P_{O}\right)^{c}=\left(P_{I}^{\perp}\right)^{c}=P,\left(P_{I}\right)^{c}=\left(P_{O}^{\perp}\right)^{c}=P^{\perp}$ for propositional letters $P$;
- writing proofs in the sequent calculus with "right-hand sequents" only.
(ii) Unfortunately, in general it is not true that $\left((A)_{O}\right)^{c}=A$, e.g., let $A$ be $\perp$.

## 3. Chu's construction

We follow the categorical semantics for IMLL in [5]:
Theorem 6 Let A be the free *-autonomous category on a set of objects $\{P$, $\left.P^{\prime}, \ldots\right\}$ and let $C$ be the symmetric monoidal closed category with products, free on the set of objects $\left\{P_{O}, P_{I}, P_{O}^{\prime}, P_{I}^{\prime}, \ldots\right\}$ (a pair $P_{O}, P_{I}$ for each atom $P$ of $A$ ).
(i) We can give $C \times C^{o p}$ the structure of $a^{*}$-autonomous category thus:

$$
\left(X_{O}, X_{I}\right) \otimes\left(Y_{O}, Y_{I}\right)={ }_{d f}\left(X_{O} \otimes Y_{O},\left(X_{O} \multimap Y_{I}\right) \times\left(Y_{O} \multimap X_{I}\right)\right)
$$

with unit $(\mathbf{1}, \top)$ and involution $\left(X_{O}, X_{I}\right)^{\perp}={ }_{d f}\left(X_{I}, X_{O}\right)$
where 1 is the unit of $\otimes$ in $C$ and $T$ the terminal object of $C$.
Therefore there is a functor $F$ from $A$ to $\left(C \times C^{o p}\right)$ sending an object $P$ to $\left(P_{O}, P_{I}\right)$. If $\pi: I \rightarrow \wp(\Gamma)$ is a morphism of $A$ represented as a proof-net
$\mathcal{R}$ with conclusions $\Gamma$, then the morphism $(\mathbf{1}, \mathrm{T}) \rightarrow\left(\wp(\Gamma)_{O}, \wp(\Gamma)_{I}\right)$ is given by all the Girard's trips on $\mathcal{R}$, in the precise sense spelt out in Proposition 15 below.
(ii) If in addition $C$ has also coproducts, then $\left(C \times C^{o p}\right)$ has also products:

$$
\left(X_{O}, X_{I}\right) \&\left(Y_{O}, Y_{I}\right)=d f\left(X_{O} \& Y_{O}, X_{I} \oplus Y_{I}\right) .
$$

The functor $F$ preserves also the structure of the products.
Proof. [Sketch] In $C \times C^{\circ p_{\text {lefine }}} \quad X \wp Y={ }_{d f}\left(X^{\perp} \otimes Y^{\perp}\right)^{\perp}$ and $\quad X \multimap Y={ }_{d f}$ $X^{\perp} \wp Y$ and show that $X \multimap Y$ gives the closed structure for $\otimes$. By the definitions

$$
(V, Y) \multimap(W, Z)=((V \multimap W) \times(Z \multimap Y), V \otimes Z)
$$

We exhibit a natural bijection of hom-sets

$$
(U, X) \otimes(V, Y) \rightarrow(W, Z) \quad \sim \quad(U, X) \rightarrow(V, Y) \multimap(W, Z)
$$

Indeed a map in $(U, X) \otimes(V, Y) \rightarrow(W, Z)$ consists of a map $a: U \otimes V \rightarrow W$ and of a pair of maps $b: Z \rightarrow U \multimap Y, c: Z \rightarrow V \multimap X$; a map in $(U, X) \rightarrow(V, Y) \multimap(W, Z)$ consists of a pair of maps $a^{\prime}: U \rightarrow V \multimap W$, $b^{\prime}: U \rightarrow Z \multimap Y$ and of a map $c^{\prime}: V \otimes Z \rightarrow X$. But $a \mapsto a^{\prime}$ and $c \mapsto c^{\prime}$ by the natural bijections given by the symmetric monoidal closed structure of C. Similarly, there is a natural bijection $\eta$ between $Z \rightarrow U \multimap Y$ and $Z \otimes U \rightarrow Y$ and also a natural bijection $\eta^{\prime}$ between $Z \otimes U \rightarrow Y$ and $U \rightarrow Z \multimap Y$; composing $\eta^{\prime}$ and $\eta$ we get $b \mapsto b^{\prime}$. Therefore $\multimap$ is a right adjoint for $\otimes$ in $C \times C^{o p}$.

To see how the action of the functor is given by Girard's trips in the case of CMLL without units, the proof in [8], pp. 37-44, (briefly reviewed in the following section) shows that a Danos-Regnier graph on a cut-free proof-net $\mathcal{R}$ with conclusions $\Gamma, \mathbf{C}$ (with $\mathbf{C}$ the selected conclusion) determines an orientation (polarization) $\delta$ of the formulas in the proof-net and a reduced translation of $\mathcal{R}$ into a cut-free derivation $\pi^{\delta}$ of $\Gamma_{I}^{\delta} \vdash C_{\delta}^{\delta}$ inIMLL ${ }^{-}$. (The same result holds if we start with a Girard trip, as indicated below; indeed each Girard trip uniquely determines a Danos-Regnier graph.)

Now it is easy to see that a derivation $\pi^{\delta}$ can also be obtained as follows: consider the IMALL derivation $F(\mathcal{R})$ given by the trip translation of (a sequentialization of) $\mathcal{R}$ and remove all $\&$-left and $\&$-right inferences, modifying the formulas in the derivation accordingly. The result is a family $\mathcal{F}$ of $\mathbf{I M L L}^{-}$ derivations, a pair of derivations for each \&-right application in $F(\mathcal{R})$. Every derivation $\pi^{\delta}$ determined by some Danos-Regnier switching is equivalent modulo permutations of inferences with one derivation in $\mathcal{F}$ and, moreover, every derivation in $\mathcal{F}$ is equivalent to a derivation $\boldsymbol{\pi}^{\delta}$ for some $\delta$ induced
by a Danos-Regnier switching. (in the terminology of Proposition 15 below we have: $\mathcal{F}=\left\{\sigma_{s_{1} \mathcal{R}}[F(\mathcal{R})], \ldots, \sigma_{s_{k} \mathcal{R}}[F(\mathcal{R})]\right\}$ where $s_{1}, \ldots, s_{k}$ are all the Danos-Regnier switchings of $\mathcal{R}$.)

A simpler formulation of the above result could be given by mapping proofnets for classical MLL ${ }^{-}$to F. Lamarche and A. Tan's proof-nets for intuitionistic $\mathbf{M L L}{ }^{-}$(see [20, 26]). For an extension to CMLL with units and to CMALL, see Remarks 7 and 17 below.

Remark 7 (i) The functor $F$ is not full. For instance, $F(\perp)=(T, \mathbf{1})$, and there is a morphism $F(\mathbf{1}) \rightarrow F(\perp)$ in $C \times C^{o p}$, namely, the map $t \times t^{\prime}$ : $(1, T) \rightarrow(T, \mathbf{1})$, where $t^{\prime}: \top \rightarrow \mathbf{1}={ }_{d f} t: \mathbf{1} \rightarrow \mathrm{T}$; however, the free category $A$ does not have a morphism $\mathbf{1} \rightarrow \perp$, i.e., $\perp$ is not provable in MLL. The system CLL $+\perp=\mathbf{1}$ has been studied, e.g., in [14], and perhaps this extension of linear logic deserves further consideration, but it is not the answer to our concern here. The task is rather to characterize a subcategory of $C \times C^{o p}$ for which the functor $F$ is full.
(ii) Is the functor $F$ is faithful? This question raises the issue of the identity of proofs in linear logic. Proof-nets provide a solution to this problem for the multiplicative fragment without units, because in this fragment proof-nets represent sequent derivations up to permutations of inferences and the ChurchRosser property holds strictly (see the next section). Notice that in [5] cut reductions in IMALL correspond to $\beta \eta$ equality of the terms which express the maps in the free symmetric monoidal closed category and commutative conversions correspond to natural isomorphisms between them. If in $C \times C^{o p}$ we consider terms up to $\beta \eta$ equivalence, then faithfulness is obtained by making the corresponding assumption about $A$, i.e., by stipulating that the morphisms of $A$ are represented by proof-nets up to cut-elimination and $\eta$-equivalence. For an extension to this result to MLL with units, see the note in Section 4.4. However, in the case of proof-nets for MALL the notion of identity of proofs is not well-understood, and thus the issue of faithfulness must be left to further research.

## 4. Proof-nets, trips and translations

In this section we summarize some results about proof-nets that illustrate the geometric connections between Girard's trips and translations into fragments of intuitionistic linear logic.

### 4.1 Proof-nets: basic definitions

Definition 8 (i) Proof-structures for CMALL are directed graphs with at least one external point and where each vertex is typed and has the form indicated in Figure 2.1. The dashed line in a $\perp$-vertex is called an attachment. When a
$\perp$-link is attached to an edge $A$, we may think of the attachment as resulting from an axiom $\perp, \mathbf{1}$ linked to a times link $\mathbf{1} \otimes A$, i.e., as an application of the isomorphism $A \sim A \otimes \mathbb{1}$.

Figure 2.1. Links
(ii) On proof-structures for CMLL Girard's trips are defined according to the drawings in Figure 2.2; the choice of the form of a trip at a par link is called a left or right switch. Proof-nets for MLL are proof-structures satisfying Girard's no-short-trip condition, namely, that for every switching of the par links and every conclusion $C$, the trip starting at $C$ returns to $C$ after visiting each edge precisely twice (cf. [16])

Figure 2.2. Girard's trips
(iii) Perhaps more familiar is the equivalent characterization of proof-nets for $\mathbf{M L L}{ }^{-}$in terms of Danos-Regnier graphs [10] (which is readily extended to MLL with units using attachments as above). Given a proof-net $\mathcal{R}$ for $\mathbf{M L L}{ }^{-}$,
a switching sof $\mathcal{R}$ in the sense of Danos-Regnier is an assigment to each par link in $\mathcal{R}$ of a choice of the left or right premise and, moreover, a "pointing" of the conclusions $\Gamma$ of $\mathcal{R}$. Given a proof-net $\mathcal{R}$ and a switching $s$ of it, the Danos-Regnier graph $s \mathcal{R}$ (determined by ,s) is the graph resulting from $\mathcal{R}$ by removing the edge which enters a par link from the premise which is not selected by $s$. The standard correctness condition for MLL ${ }^{-}$proof-nets is the following: a proof-structure $\mathcal{R}$ for $\mathbf{M L} \mathbf{L}^{-}$is a proof-net if for every switching $s$ the Danos-Regnier graph $s \mathcal{R}$ is acyclic and connected (an undirected tree).

In the case of CMALL we have true boxes which behave like $n+1$-ary axioms. Moreover, a boolean valued polynomial is associated with each edge, a distinct boolean variable $x$ is associated with each with link, $x$ and $1-x$ being added to the polynomials associated with the left and right premise of the with link in question. The polynomial of the conclusion of a link is the sum of the polynomials of the premises. All the conclusions of the proof-net must have 1 as associated polynomial. A proof structure is sliced by substituting arbitrary boolean values for the variables and erasing the edges whose polynomial evaluates to 0 ; in a sliced proof-structure additive links are all unary. (For a more precise definition, of additive proof-nets, see Girard [18].) All said, a CMALL proof-structure is a proof-net if for every evaluation of the polynomials, the resulting slice has no short trip.

What matters here is that the following theorem can be proved:

Girard's Theorem. There exists a 'context-forgetting' map ( )- from sequent derivations in MALL to proof-nets with thefollowing properties:
(a) Let $d$ be a sequent derivation of $\vdash \Gamma$; then ( ()$^{-}$is a proof-net with conclusion $\Gamma$;
(b) (Sequentialization) If $\mathcal{R}$ is a proof-net with conclusion $\Gamma$, then there is a sequent calculus derivation $d$ of $\vdash \Gamma$ such that $\mathcal{R}=(\mathrm{d})^{-}$.

About proof-nets for $\mathbf{M L L} \mathbf{L}^{-}$more can be proved (see [9], Theorem 2):
Permutability of Inferences Theorem. Let $d$ and $d^{\prime}$ be a pair of derivations of the same sequent $\vdash \Gamma$ in $\mathbf{M L L} \mathbf{L}^{-}$. Then $(d)^{-}=\left(d^{\prime}\right)^{-}$if and only if there exists a sequence of derivations $d=d_{1}, d_{2}, \ldots, d_{n}=d^{\prime}$ such that $d_{i}$ and $d_{i+1}$ differ only for a permutation of consecutive inferences.

Remark 9 A corollary of the latter theorem is that the syntax of proof-nets for $\mathbf{M L L}{ }^{-}$solves the problem of identity of proofs in this fragment; for this reason proof-nets have found applications to coherence problems in category theory.

### 4.2 Trips and linear $\boldsymbol{\lambda}$ terms

A trip in the sense of Girard induces the structure of a $\lambda$-term in any suitable graph with a selected external point (pointed graph):

Theorem 10 (J. van de Wiele) Every connected pointed graph with vertices of incidence 1 and 3 corresponds to a linear $\lambda$-term (and vice versa). The correspondence is established in linear time by a trip starting with the selected external point.

We perform a trip in the style of Girard according to the figure below; during the trip we determine whether a vertex is to be regarded as (1) a variable, (2) an application or (3) a $\lambda$-abstraction. Case (2) occurs when during the second visit to a vertex of incidence 3 the trip enters the vertex through the same edge from which it had exited after the first visit; case (3) occurs when the second visit is through the other edge; case (1) is that of an external vertex different from the selected one.
variable:

Figure 2.3. Linear $\lambda$-terms

The proof is by induction on the number of vertices. Notice that if we remove the first vertex of incidence 3 encountered during the trip then the resulting graph is disconnected in case (2) but remains connected in case (3). Different variables are assigned to different external points in case (1). Since linear $\lambda$-terms are always typable, van de Wiele's result also shows that every such connected pointed graph corresponds to a proof in the implicative fragment of intuitionistic linear logic.

### 4.3 Reduced translations from CMLL $^{-}$to IMLL $^{-}$

Essentially the same technique applied to a proof-net for CMLL ${ }^{-}$yields a translation of the proof-net into a derivation in the implication and tensor fragment of intuitionistic multiplicative linear logic. These translations shall be called reduced trip translations or simply reduced translations. Trips always
have a starting point in a conclusion and the order of the passages across a link matters. To state our result we need a definition.

Definition 11 Given a proof-net $\mathcal{R}$ for $\mathbf{C M L L}^{-}$and a selected conclusion $A$, we say that a Girard trip starting from $A$ is covariant on an edge if the second passage of the trip is in the same direction as the edge; otherwise, the trip is contravariant on the edge. Now a trip starting from $A$ induces an input-output orientation $\delta: \mathcal{R} \rightarrow\{I, O\}$ thus: an edge $X$ is an output $X_{O}$ or an input $X_{I}$ depending on whether the trip is covariant or contravariant on it.

Theorem 12 (Bellin and van de Wiele) (i) Every Girard's trip on a cut-free proof-net for $\mathbf{C M L} \mathbf{L}^{-}$starting from a selected conclusion corresponds to a sequent calculus derivation in $\mathbf{I M L L}{ }^{-}$.
(ii) Conversely, every sequent derivation in $\mathbf{I M L L}^{-}$corresponds to a trip on a proof-net.

The following proposition follows almost immediately from the definition of orientation and the basic properties of trips.

Proposition 13 Every orientation makes the selected conclusion an output, all other conclusions are inputs. Every link is oriented in one of the admissible ways indicated in Figure 2.4.
axiom:

false:

par: left switch

boxes:

Figure 2.4. Admissible orientations.

Given an orientation $\delta: \mathcal{S} \rightarrow\{I, O\}$, the formulas in the proof-net are translated as follows:

For further details, see [8], pp. 37-44.
Remark 14 (i) Theorem 12 could be stated in terms of Danos-Regnier graphs, as it was done in [8]; notice that every Girard's trip determines a unique DanosRegnier graph [10]. Girard's trips allow us to give a more concise definition of orientation, but Danos and Regnier's characterization yields the refinements in Proposition 15 below.
(ii) Reduced translations of formulas are not functorial, in the sense that they depend not only on the given CMLL formula, but also on a trip on a given proof; i.e., the map on objects depends also on morphisms. Reduced translations of proofs are not functorial, in the sense that they may not be compatible with cut. Indeed, the orientation induced by a switching may be computationally inconsistent: e.g., consider the orientation on the cut formulas $A_{O} \otimes B_{I}$ and $A_{O}^{\perp} \wp B_{I}^{\perp}$ induced by a left switch on the par link.
(iii) The above result does not extend to full CMLL: let $\perp$ be the selected conclusion in the cut-free proof-net with conclusion $P, P^{\perp}, \perp$.
(iv) The above result does not extend to CMALL: consider the cut-free proofnet with conclusions $A \& B, A^{\perp} \otimes B^{\perp}, A \oplus B$.

However, reduced translations suffice to characterize the action of the functor $F$ of theorem 6 on a derivation in the fragment $\mathbf{M L} \mathbf{L}^{-}$in the following sense. Let $s$ be a switching in the sense of Danos-Regnier on a proof-net R for $\mathbf{M L L} \mathbf{L}^{-}$. Let IMALL ${ }^{-}$be IMALL without plus. Consider the set of maps $\sigma: \mathbf{I M A L L}^{-} \rightarrow \mathbf{I M L L}^{-}$with the following properties:
(a) $\sigma$ acts on the propositions as follows:

$$
\begin{array}{lll}
\sigma\left[\left(A_{I} \multimap B_{O}\right) \&\left(B_{I}-o A_{O}\right)\right]=\sigma\left[A_{I}-o B_{O}\right] & \text { or } & \sigma\left[B_{I} \multimap A_{O}\right] \\
\sigma\left[\left(A_{O} \multimap B_{I}\right) \&\left(B_{O} \multimap A_{I}\right)\right]=\sigma\left[A_{O} \multimap B_{I}\right] & \text { or } & \sigma\left[B_{O} \multimap A_{I}\right] \tag{ii}
\end{array}
$$

(b) $\sigma$ acts on IMALL ${ }^{-}$derivations $\pi$ by removing all $\&$-right and $\&$-left inferences

Clearly, given such a $\sigma$ defined arbitrarily on propositions we do not know whether there is a proof $\pi$ of $\vdash(\wp(\Gamma))_{O}$ such that $\sigma(\pi)$ is a proof of $\vdash$ $\sigma\left[(\wp(\Gamma))_{O}\right]$. Moreover, given any derivation $\pi$ in IMALL $^{-}, \sigma[\pi]$ needs not
be a derivation in $\mathbf{I M L L}{ }^{-}$(for instance, if the map on derivation removes a \&left inference with active formula $\sigma\left[A_{O} \multimap B_{I}\right]$ and the map on propositions yields $\sigma\left[B_{O} \multimap A_{I}\right]$ ). However, Danos-Regnier switchings allow us to define well-behaved maps $\sigma$ as functions of a proof-net and of a switchings.

Proposition 15 Let $\mathcal{R}$ be a cut-free proof-net for $\mathbf{M L L}^{-}$with conclusions $\Gamma$ and let $s$ be a Danos-Regnier switching of $\mathcal{R}$. Let $\pi$ be the derivation of $\vdash(\wp(\Gamma))_{o}$ in $\mathbf{I M A L L}{ }^{-}$given by the Chu functor. Then there exists a map $\sigma_{s} \mathcal{R}$ such that $\sigma_{s \mathcal{R}}[\pi]$ is a derivation of $\sigma_{s \mathcal{R}}\left[(\wp(\Gamma))_{o}\right]$ in $\mathbf{I M L L}{ }^{-}$. Moreover,
$\sigma_{s \mathcal{R}}\left[\left(A_{I} \multimap B_{O}\right) \&\left(B_{I} \multimap A_{O}\right)\right]=\sigma_{s \mathcal{R}}\left[A_{I} \multimap B_{O}\right] \quad$ iff $\quad s\left(A_{\wp} B\right)=$ right.
Remark 16 (i) It can be shown that and the map $\sigma_{s \mathcal{R}}$ depends only on the values of $s$ on the par links which in a Girard trip are reached from below, i.e., the par links whose conclusion is oriented as an "output" and which correspond to formula-occurrences of type (i) in $\pi$.
(ii) Let $\pi$ be a reduced translation in $\mathbf{I M L L}{ }^{-}$of a derivation $d$ in $\mathbf{M L L}^{-}$and let $(\pi)^{c}$ be its translation back to MLL ${ }^{-}$according to Fact 5 . Then $d$ and $(\pi)^{c}$ are equal (possibly modulo permutations of inferences).

### 4.4 Chu's construction in MLL with units

As indicated in the Preface, one of the original motivations for this paper was to find a functorial definition of the trip translation, in view of a possible extension to the whole system CLL and given the fact that the reduced trip translation does not extend beyond MLL ${ }^{-}$. We have now a functorial translation and a satisfactory explanation of its meaning in terms of Chu's construction. But what about extensions to MLL with units and CMALL?

As indicated in Remark 7, the problem with fullness may require a basic reformulation of the construction, e.g., the definition of a subcategory of $C \times C^{o p}$ for which the functor is full. Moreover, faithfulness for CMALL requires a reconsideration of additive proof-nets. On the other hand, the proof of faithfulness for MLL with units seems at hand, thanks to A. Tan's thesis [26], although we cannot spell out the details here.

Remark 17 (MLL with units) (i) We do not know how to define proof-nets for MLL with units so as to extend the theorem on Permutability of Inferences to MLL with units, thus it is no longer true that the the proof-net representation solves the problem of identity of proofs in MLL with units (cf. Remark 9). Any permutation of the nil rule with other inferences in a derivation $d$ results in a rewiring of $(d)^{\text {- }}$, i.e., in a modification of the 'attachment' of the corresponding $\perp$-link. (Of course, this problem would not occur in the system MLL
with the axiom $\perp=1$.) Therefore the obvious way to characterize the identity of proofs for MLL with units is to give explicit equations between proof-nets.
(ii) A similar problem occurs for the representation of proofs in IMLL: in fact the systems of Natural Deduction or Sequent Calculi with term-assignments for ILL in $[4,5,6]$ are given together with an axiomatic characterization of the identity of proofs in the form of an equational theory of terms. Similarly, Lamarche's proof-nets for ILL [20] require a theory of rewiring already in the case of MLL with units. This work has been done in Chapter 6 of A. Tan's thesis [26]: after a careful definition of the correspondence between sequent calculus with term assignments and proof-nets for IMLL, the process of rewiring is defined so that it does preserves the correctness criterion, it does not affect the (equivalence classes of) terms which the proof-net interprets, it is strongly normalizing and confluent and, moreover, the process of cut-elimination, incorporating unit rewirings, remains strongly normalizing and confluent.
(iii) Rewiring in CMLL proof-nets is also defined in such a way that it preserves the correctness criterion. Since classical proof-nets may have several conclusions, it is not obvious how to define a canonical element in each equivalence class of proof-nets.
(iv) Let us consider the again action of the functor $F:$ CMLL $\rightarrow$ IMALL on the units. If $\pi$ is a proof of $\vdash \Gamma, \perp$, then $F(\pi)=\Gamma_{I} \vdash \mathrm{~T}$, an axiom, i.e., the proof $\pi$ is erased. It follows that a single reduced translation, regarded as a CMLL proof, no longer contains the same information as the original proof (cf. Remark 16.(ii)).
(v) Considering the definition of reduced translations from Danos-Regnier graphs, we may follow the hint of Definition 8.(i) and define the orientation as if an attachment resulted from an axiom $\perp, \mathbf{1}$ where the edge $\mathbf{1}$ enters a times link with conclusion $\mathbf{1} \otimes A \sim A$. The definition extends without problems when the orientation of $\perp$ is $\perp_{I}$ : indeed the corresponding IMLL proof-net has a 1 -link with a suitable attachment. If the orientation is $\perp_{O}$ we may no longer have a coherent orientation for the edge $A$ (in the case where we would give the different orientations $\left.A_{O},(1 \otimes A)_{I}\right)$ : but this is still fine, because $\boldsymbol{F}\left(\perp_{O}\right)=\mathrm{T}$ and we may certainly take an axiom $\mathrm{T}, A_{I}, A_{O}$ in the reduced translation.
(vi) Finally, let us consider the effect of rewiring of CMLL proof-nets $\mathcal{R} \mapsto \mathcal{R}^{\prime}$ on a reduced trip translation of $\mathcal{R}$. Given a $\perp$ link in $\mathcal{R}$, the rewiring in question may
(1) preserve the orientation $\perp_{I}$ or
(2) preserve the orientation $\perp_{O}$ or
(3) change an orientation $\perp_{I}$ into $\perp_{O}$ or
(4) vice versa.

In case (1) the effect of the rewiring is either null or a rewiring in IMLL as described in [26]. In case (2) the effect is either null or a commutation of a $T$ axiom, in accordance with standard equations between IMALL-proofs. Only cases (3) and (4) do reserve some surprises; e.g., in case (iii) the IMLL proofnet resulting from a switching $\check{s} \mathcal{R}^{\prime}$ may be obtained from the IMLLproof-net corresponding to $s \mathcal{R}$ only through some complicated "surgery".
