**ABSTRACT**

Pulmonary-artery-hypertension (PAH) is a life-threatening and highly invalidating chronic disorder. Chronic oxidation contributes to lung damage and disease progression. Peroxiredoxin-2 (Prx2) is a typical 2-cysteine (Cys) peroxiredoxin but its role on lung homeostasis is yet to be fully defined. Here, we showed that Prx2−/− mice displayed chronic lung inflammatory disease associated with (i) abnormal pulmonary vascular dysfunction; and (ii) increased markers of extracellular-matrix remodeling. Hypoxia was used to induce PAH. We focused on the early phase PAH to dissect the role of Prx2 in generation of PAH. Hypoxic Prx2−/− mice showed (i) amplified inflammatory response combined with cytokine storm; (ii) vascular activation and dysfunction; (iii) increased PDGF-B lung levels, as marker of extracellular-matrix deposition and remodeling; and (iv) ER stress with activation of UPR system and autophagy. Rescue experiments with in vivo the administration of fused-recombinant-PEP-Prx2 show a reduction in pulmonary inflammatory vasculopathy and in ER stress with down-regulation of autophagy. Thus, we propose Prx2 plays a pivotal role in the early stage of PAH as multimodal cytoprotector, targeting oxidation, inflammatory vasculopathy and ER stress with inhibition of autophagy. Collectively, our data indicate that Prx2 is able to interrupt the hypoxia induced vicious cycle involving oxidation-inflammation-autophagy in the pathogenesis of PAH.

1. Introduction

Pulmonary artery hypertension (PAH) is a life threatening highly invalidating chronic disorder [1–3]. Although in the last decade progresses have been made in the identifications of factors involved in its pathogenesis, much still remains to be investigated in the mechanism involved in the early stage of PAH [3–5]. Regardless of the initial event, the combination of chronic inflammation and chronic...
hypoxia promote a high pro-oxidant environment, mediating disease progression [1,2,4,6,7].

In this scenario, efficient catabolic pathways to either buildup misfolded/unfolded proteins or to clear intracellular damaged proteins are required [8–11]. Studies in different models of PAH have shown that cellular response to face the accumulation of damaged proteins is mainly through endoplasmic reticulum (ER) stress followed by the activation of autophagy to clear damaged proteins and to reduce ER stress [10,12,13]. Indeed, classic chaperones such as heat shock protein 90 and 70 (HSP) are upregulated in PAH, indicating the requirement of chaperone systems to deal with the accumulation of damaged proteins [14].

Prx2 is a typical 2-cysteine (Cys) peroxiredoxin ubiquitously expressed. Prx2 has been largely investigated in erythroid cells, where it is approved the experimental protocols. Where indicated WT and Prx2−/− University of Verona (CIRSAL) and by the Italian Ministry of Health hypertension in mice genetically lacking Prx2 (Prx2−/−), using hypoxic model of ischemic/reperfusion stress highlighted the key role of Prx2 as antioxidant system [24,25].

Here, we studied the role of Prx2 in development of pulmonary hypertension in mice genetically lacking Prx2 (Prx2−/−), using hypoxic stress to explore the early stage of early phase of pulmonary hypertension. Our data collectively indicate that Prx2 plays a pivotal role in the early phase of hypoxia induced pulmonary hypertension as antioxidant system and chaperone. The administration of Prx2 fused to cell-penetrating carrier PEP (cell penetrating peptide; PEP Prx2; [19]) (i) reduces local and systemic inflammation; (ii) prevents vascular activation and PDGF-B up-regulation; (iii) alleviates ER stress and (i) down-regulates autophagy activation in response to hypoxia. Thus, PEP Prx2 might represent an interesting new multimodal therapeutic option in the early stage PAH.

2. Materials and methods

2.1. Drugs and chemicals

Details are reported in Supplemental materials and methods.

2.2. Mouse strains and design of the study

C57B6/2J mice as wildtype controls (WT) and Prx2−/− mice aged between 4 and 6 months both male and female were used in the present study [19,26]. The Institutional Animal Experimental Committee, University of Verona (CIRSAL) and by the Italian Ministry of Health approved the experimental protocols. Where indicated WT and Prx2−/− mice were treated with 1) N-Acetyl-Cysteine (NAC) (NAC) at the dosage of 100 mg/kg/d (in NaCl 0.9%, NaOH 36 mM, pH 9.4; ip) or vehicle only for 3 weeks [19,20]; 2) PEP Prx2 (in PBS) or vehicle at the dosage of 3 mg/kg/d ip or vehicle for 4 weeks before and during hypoxia [19]. Whenever indicated, mice were exposed to hypoxia (8% oxygen for 10 h, 3 days, 7 days) (Hy) as previously described [27–29]. To collect organs, animals were first anesthetized with isoflurane, bronchoalveolar lavage (BAL) was collected and then mice were euthanized. Organs were immediately removed and divided into two and either immediately frozen in liquid nitrogen or fixed in 10% formalin and embedded in paraffin for histology.

2.2.1. Bronchoalveolar lavage (BAL) measurements

BAL fluids were collected and cellular contents were recovered by centrifugation and counted by microcytometry as previously reported [27]. Percentage of neutrophils was determined on cytospin centrifugation. Remaining BAL samples were centrifuged at 1500 ×g for 10 min at 4 °C. The supernatant fluids were used for determination of total protein content [27].

2.3. Lung molecular analysis

2.3.1. Lung histology

Multiple (at least five) three-micron whole mount sections were obtained for each paraffin-embedded lung and stained with hematoxylin eosin, Masson’s trichome, and May-Grünwald-Giemsa. α-smooth muscle actin immunohistochemistry (IHC) on lungs was carried out as previously reported [27,30]. Lung pathological analysis was carried out by blinded pathologists as previously described [27,30]. Based on previous reports (18, 38), the pathological criteria for lung histopathology were as follows: i) Bronchus: Mucus: 0: no mucus; + : mucus filling less than 50% of the area of the bronchus section; + + : mucus filling more than 50% of the area of the bronchus section. (ii) Inflammatory infiltrate density: 0: less than 5 inflammatory cells per field; +: 5–30 inflammatory cells per field; + + more than 30 inflammatory cells per field. (iii) Thrombi: 0: no thrombus; +: presence of a thrombus in one field, at magnification 250.

2.3.2. Immunoblot analysis

Frozen lung and heart from each studied group were homogenized and lysed with iced lyses buffer (LB containing: 150 mM NaCl, 25 mM bicine, 0.1% SDS, Triton 2%, EDTA 1 mM, protease inhibitor cocktail tablets (Roche), 1 mM Na3VO4 final concentration) then centrifuged 10 min at 4 °C at 12,000g. Proteins were quantified and analyzed by mono-dimensional SDS polyacrylamide gel electrophoresis. Gels were transferred to nitrocellulose membranes for immuno-blot analysis with specific antibody. Details are reported in Supplemental materials and methods [21,27,31–33]. Whenever indicated Prx2 dimerization was studied in lung from PBS perfused mice containing 100 mM NEM, using an approach similar to that reported by Kumar et al. [34].

2.3.3. RNA isolation, cDNA preparation and quantitative RT-PCR

Total RNA was extracted from tissues using Trizol reagent (Life Technologies, Monza, Italy). Synthesis of cDNA from total RNA (1 μg) was performed using Super Script II First Strand kits (Life Technologies). Quantitative RT-PCR (qRT-PCR) was performed using the SYBR-green method, following standard protocols with an Applied Biosystems ABI PRISM 7900HT Sequence Detection system. Relative gene expression was calculated using the 2−(ΔΔCt) method, where ΔCt indicates the differences in the mean Ct between selected genes and the internal control (GAPDH). qRT-PCR primers for each gene were designed with Primer Express 2.0 (Life Technologies) (primer sequences are reported in Table 1S) [27,30].

2.4. MDA assay

MDA was determined as previously reported [35].

2.5. Evaluation of right ventricular hypertrophy and echocardiography measurements

Hearts were fixed with 10% formaldehyde for 24 h. The right ventricular (RV) free wall was separated from the left ventricle with septum (LV+S) under dissection microscope. RV and LV + S were separately weighed and used to calculate the ratios RV/(LV + S)/body weight [36]. Transthoracic echocardiography was performed with a Vevo 2100 echocardiograph (Visual Sonic, Toronto, Canada) equipped with a 22–55 MHz transducer (MicroScan Transducers, MS500D) as previously reported [27,37].

2.6. Statistical analysis

Data were analyzed using either t-test or the 2-way analysis of
variance (ANOVA) for repeated measures between the mice of various genotypes. A difference with a P value less than 0.05 was considered significant.

3. Results

3.1. Mice genetically lacking Prx2 show lung inflammation, increased pulmonary vascular activation and extracellular-matrix remodeling

Lung histopathologic analysis showed increased peribronchial edema in Prx2−/− mice under normoxic condition compared to wildtype animals (Fig. 1A, upper panel). The systematic study for α-smooth cells expression showed a staining in broken line only on bronchial sections of Prx2−/− mice, suggesting an initial pulmonary vessel muscularization (Fig. 1A, lower panel). Increased bronchoalveolar lavage (BAL) levels of proteins and of total leukocytes were detected in Prx2−/− mice compared to wildtype, indicating an abnormal pulmonary vascular leakage (Fig. 1SA).

In Prx2−/− mice, we observed increased active form of NF-kB and Nrf2, two redox related transcriptional factors, compared to wildtype animal (Fig. 1B). This was associated with increased lung MDA levels (Fig. 1SB) and up-regulation of the pro-inflammatory cytokines IL-6, IL-1β, IL-10 that are known targets of NF-kB (Fig. 1C). We confirmed the increased expression of IL-6 by immunoblot analysis in lung from Prx2−/− mice compared to wildtype animals (Fig. 1D). The activation of Nrf2 in the absence of Prx2 was supported by the up-regulation of Nrf2 related systems such as HO-1, a vascular and lung cytoprotector, and SOD-1, a potent anti-oxidant enzyme supports (Fig. 1D)[38]. We also observed higher levels of (i) endothelin-1 (ET-1), the most potent vasoconstrictive and broncho-constrictive cytokine [30]; (ii) VCAM-1, a marker of vascular endothelial activation [27]; and (iii) PDGF-B, a known factor involved in lung extracellular matrix remodeling [39] (Fig. 1D).

These data link the absence of Prx2 with persistent lung inflammation, endothelial vascular activation, and extracellular matrix remodeling.
3.2. Prolonged hypoxia promotes the development of early stage pulmonary hypertension in Prx2-/- mice

Based on our previous report, showing the development of early stage PAH in a mouse model for sickle cell disease but not in wildtype mice [36], we exposed both mouse strains to hypoxia (Hy) 8% oxygen for 7 days. As shown in Fig. 2A, hypoxia induced sparse inflammatory infiltrate with some peribronchial edema in Prx2-/- mice (upper panel Immunohistochemistry using anti alpha actin antibody × 600). B. Representative images of mitral inflow pattern recorded by Doppler echo imaging in wildtype (WT) and Prx2-/- mice under hypoxia as in Fig. 1A. Lower panels. Average mitral valve deceleration time (left panel) and pulmonary acceleration time (PAT) to ejection time (ET) ratio (right panel). *p < 0.05 and **p < 0.01 WT vs Prx2-/- mice; #p < 0.05 and ##p < 0.01 hypoxia vs basal by one-way ANOVA followed by Newman-Keuls Multiple Comparison test. The black dashed lines have been added to the graph to favor visual comparison between the white bars to the black bars. C. Immunoblot analysis with specific antibodies against peroxiredoxin-2 (Prx2) and thioredoxin-reductase 1 (Trdx) of lung wildtype (WT) and Prx2-/- mice under normoxia (N) exposed to hypoxia (Hy) for 10 h (10 h), 3 days (3D), 7 days (7D). One representative gel from six with similar results is presented. Densitometric analysis of immunoblots is shown in Fig. 2SA. D. Immunoblot analysis with specific antibodies against phospho-NF-kB (P-NF-kB), NF-kB, phospho-Nrf2 (P-Nrf2) and Nrf2 of lung wildtype (WT) and Prx2-/- mice under normoxia (N) and exposed to hypoxia (Hy) for 10 h (10 h), 3 days (3D), 7 days (7D). One representative gel from six with similar results is presented. Densitometric analysis of immunoblots is shown in Fig. 2SB.

3.3. Prx2 plays an important role as cytoprotective system against hypoxia induced PAH

In order to follow-up the generation of PAH in Prx2-/- mice, we studied both mouse strains at different time intervals between 0 to 7-days hypoxia to identify the optimal window-time to analyze
mechanism(s) involved in development of PAH. BAL protein and leukocyte count were significantly increased in Prx2<sup>−/−</sup> mice during hypoxia at 10 h, 3 days and 7 days compared to wildtype animals (data not shown).

Hypoxia markedly increased Prx2 expression in lung from wildtype mice at 10 h, 3 days and 7 days of exposure (Fig. 2C, Fig. 2SA). This was associated with time dependent increased expression of thioredoxin-reductase, a Prx2 repairing system (Trdx; Fig. 2C; Fig. 2SA). The modulation of Trdx expression during hypoxia even in the absence of Prx2, may be possible related to the fact that Trdx is part of different NADPH-dependent pathways [19,40].

In Prx2<sup>−/−</sup> mice exposed to hypoxia, we observed a rapid and sustained activation of Nrf2 in response to hypoxia, while there was a reduction in activation of NF-kb (Fig. 2D, 2SB). Otherwise, wildtype mice showed an early response of Nrf2 at 10 and 3-h hypoxia, partially overlapping the activation of NF-kb observed at 3 and 7 days hypoxia (Figs. 2D, 2SB). These data suggest that Nrf2 might be a precocious back-up mechanism in response to hypoxia, which is early activated in both mouse strains, but to higher extent in mice genetically lacking Prx2.

Since pro-inflammatory cytokines are modulated by oxidation and participates to the development of PAH [3,41,42], we evaluated IL1b and IL6 expression in lung from both mouse strains during hypoxia. In wildtype animals at 3 days hypoxia compared to normoxic Prx2<sup>−/−</sup> animals (Fig. 4B). Wildtype animals show an early signs of ER stress with up-regulation of ATF6 and Xbp1 at 10-h hypoxia, with no major change in chronic hypoxia (Fig. 4B). It is of note that in lung from wildtype mice, we found Prx2 organized in multimers, possible reflecting the acquisition of chaperone like function (data not shown) [31,46,47].

These data indicate that the absence of Prx2 triggers ER stress during hypoxia, contributing to the early appearance of PAH in Prx2<sup>−/−</sup> mice.

3.5. PEP Prx2 treatment rescues prolonged hypoxia induced heart and lung inflammatory vasculopathy and prevents ER stress

To address the question whether Prx2 plays a role in lung chronic inflammatory disease, we firstly evaluated the impact of recombinant fusion protein PEP Prx2 (1.5 mg/kg/day ip; 3 weeks) to both mouse strains under room air condition. In normoxic Prx2<sup>−/−</sup> mice, PEP Prx2 treatment (i) prevented Nrf2 and NF-kb activation (Fig. 3SA); (ii) reduced HO-1 protein expression (Fig. 3SB); and (iii) decreased the levels of ET-1, VCAM-1 and PDGF-B (Fig. 3SB). No major changes were observed in wildtype animals (Fig. 3SA, 3SB). In order to evaluate whether the effects of PEP Prx2 treatment were specific of Prx2 or related to a general anti-oxidant effect, we treated both mouse strains with NAC (100 mg/kg/day for 3 weeks), a known anti-oxidant agent previously used in other in vitro and in vivo models of PAH [6,48]. No changes were present in the levels of Nrf2 and NF-kb activation in Prx2<sup>−/−</sup> mice treated with NAC, suggesting that the effects of PEP Prx2 are peculiar of Prx2 and not only related to its general antioxidant effects (data not shown).

In Prx2<sup>−/−</sup> mice exposed to 7 days hypoxia, PEP Prx2 treatment significantly reduced the hypoxia mediated diastolic dysfunction and ameliorated RVSP, as suggested by the increased in PAT/ET ratio (Fig. 4C, 4SA). In agreement, in heart from PEP Prx2 treated Prx2<sup>−/−</sup> mice exposed to 7 days hypoxia, we found a reduction of ANP expression as well as of markers of vascular endothelial activation (Fig. 4D). This was associated with a decrease in levels of SOD-1 and in oxidation of proteins from heart of hypoxic Prx2<sup>−/−</sup> mice treated with PEP Prx2 (Fig. 4SB). We found similar evidences of the beneficial effects of PEP Prx2 on lung from Prx2<sup>−/−</sup> mice exposed to prolonged hypoxia. As shown in Fig. 5A, PEP Prx2 promoted a significant reduction in chronic hypoxia induced increase of ANP, VCAM-1, ICAM-1 and PDGF-B levels compared to vehicle treated Prx2<sup>−/−</sup> animals. In addition, PEP Prx2 decreased the hypoxia induced ATF6 expression, suggesting a possible role of Prx2 as chaperone in agreement with the reduced expression of classic chaperone HSP70 and 90 (Fig. 5B).

To better understand the role of Prx2 in development of PAH, we chose to further study Prx2<sup>−/−</sup> mice at day 3 of hypoxia. This represents the turning point in the imbalance between oxidation/anti-oxidant activities and the activation of cellular defense mechanisms against cytotoxic effects of accumulation of damage proteins. Indeed, we found a significant increase in the amount of Prx2 dimers in lung from wildtype after 3 days hypoxia compared to normoxic wildtype animals (Fig. 4SC), supporting the role of Prx2 as H2O2 sensor generated during hypoxia as previously shown in other models [34,49].

3.6. In Prx2<sup>−/−</sup> mice, PEP Prx2 prevents the hypoxia induced oxidative stress and reduces inflammatory vascular activation and extracellular matrix remodeling

PEP Prx2 administration prevented the hypoxia induced increased in BAL protein and leukocyte content in both mouse strains (Fig. 4SD). This was associated with a marked reduction in protein oxidation state in both mouse strains exposed to 3 days hypoxia and treated with PEP Prx2, supporting the local anti-oxidant effect of exogenous PEP Prx2 treatment during hypoxia stress (Fig. 5C). In agreement, we found that PEP Prx2 administration prevented the hypoxia induced Nrf2 and NF-kB activation in both mouse strains (Fig. 5D, 5SA). This was paralleled...
by the reduction in HO-1, IL-6, ET-1, VCAM-1 and PDGF-B (Fig. 6A).

These data suggest that PEP Prx2 treatment during hypoxia is able to (i) decrease local pulmonary inflammation and oxidation; (ii) reduce systemic inflammatory response; (iii) beneficially affect hypoxia abnormalities in pulmonary vascular leakage; and (iv) prevent hypoxia activation of redox-sensitive transcriptional factors Nrf2 and NF-kB.

3.7. PEP Prx2 alleviates ER stress and down-regulates autophagy in Prx2-/- mice exposed to hypoxia

As shown in Fig. 6B, PEP Prx2 significantly down-regulated GADD34 in lung from Prx2-/- mice compared to vehicle treated animals. This was associated with a marked decrease in HSP70 and 90 expression in lung from both mouse strains exposed to 3 days hypoxia and treated with PEP Prx2 (Fig. 6C). This is agreement with previous reports on preventing PAH development by blocking ER stress with exogenous chemical chaperones [12].

Since a link between ER stress and activation of autophagy has been proposed to deal the accumulation of damaged proteins [10,44], we evaluated key elements of autophagy machinery and the effects of PEP Prx2 treatment in both mouse strains at 3 days hypoxia. Based on revision of the literature, we chose to analyze the expression of (i) autophagy related proteins ULk1 that is required for initiation of autophagy; (ii) LC3 I/II, a coordinator of phagosomal membranes and (iii) p62, a key cargo protein and component of inclusion bodies; and (iv) pro-caspase 3/caspase 3, involved in digestion of damaged proteins [9,50–52]. As shown in Fig. 7A, normoxic Prx2-/- mice showed increased LC3-II formation associated with increased expression of ULK1 and p62 compared to wildtype mice. This was associated with higher expression of pro-caspase 3/caspase 3, indicating an activation of autophagy to clear intracellular oxidative damaged proteins in Prx2-/- mice. In both mouse strains, hypoxia markedly activated autophagy as supported by increased LC3I/II expression, consumption of ULK1 and reduction of p62, suggesting a clearance of p62 positive inclusion
bodies containing damaged proteins (Fig. 7A). It is of note that the procaspase/caspase 3 ratio was also increased in both mouse models exposed to hypoxia, but to higher extent in Prx2-/- mice compared to wildtype (Fig. 7A).

As a proof of concept that Prx2 is important in the crossroad between hypoxia induced oxidation and autophagy, we evaluated the effects of PEP Prx2 treatment on autophagy in mice exposed to 3 days hypoxia. As shown in Fig. 7A, PEP Prx2 administration rescued the hypoxia induced activation of autophagy. These data indicate that Prx2 acts as multimodal cytoprotective system and is important to prevent the development of PAH.

4. Discussion

Here, we firstly show the novel role of Prx2 as lung multimodal cytoprotector against hypoxia induced PAH. Our data also indicate that Prx2 is required in management of the physiologic oxidation in lung under room air condition. In fact, normoxic Prx2-/- mice show lung chronic inflammatory vasculopathy and vascular dysfunction, associated with activation of extracellular matrix remodeling. This is in agreement with previous studies in mouse models genetically lacking other anti-oxidant systems such as SOD-1, which show increased susceptibility to both acute and chronic lung injury [53-55].
Prx2−/− mice exposed to prolonged hypoxia developed signs of PAH, combined with inflammatory vasculopathy, sustained by high ET-1 expression and increased PDGF-B levels, as markers of extracellular matrix remodeling. Both molecules have been reported to accelerate the development of hypoxia-induced PAH [30,39]. The increase in ANP lung and heart expression indicates an attempt of the endogenous system to induce pulmonary vaso-relaxation and to modulate lung and heart vascular remodeling in response to hypoxia [56,57]. This was coordinated by hypoxia-induced activation of acute phase related transcriptional factors: Nrf2 and NF-κB in both mouse strains. The early and higher activation of Nrf2 in Prx2−/− mice compared to wildtype animals, supports the role of Nrf2 as a back-up mechanism against severe oxidation in mice genetically lacking Prx2 [19]. Whereas, NF-κB seemed to be more important in prolonged hypoxia for wildtype mice compared to Prx2−/− animals. The rescue experiments with PEP Prx2 corroborate the importance of Prx2 in the functional cascade activated in response to hypoxia.

In this scenario, the absence of Prx2 favors ER stress with the activation of defensive autophagy, as important mechanisms to deal withting the accumulation of cytotoxic damaged proteins triggered by hypoxia and oxidation [10,44]. ER stress activates the UPR system, which is divided into three branches: ATF6, PERK and IRE1 [10,13]. In Prx2−/− mice, ATF6 was up-regulated in lung from animals under normoxia and after prolonged hypoxia. Whereas, GADD34, part of the PERK branch, was early up-regulated at 3 days hypoxia in Prx2−/− mice. This indicates that the absence of Prx2 favors ER stress most likely due to a reduction of endogenous chaperone power beside the increased expression of classic heat shock proteins such as HSP70 and 90 in response to hypoxia. PEP Prx2 alleviated ER stress and prevented the hypoxia-induced up-regulation of UPR system, in agreement with previous reports on exogenous chemical chaperones, reducing ER stress and preventing the development of PAH [12,13]. It is of interest to note that previous reports have shown that PDGF-B and/or ET-1 activates UPR [13,43]. In our model, the absence of Prx2 resulted in high levels of PDGF-B and ET1 that potentiate the hypoxia-induced activation of UPR system. The rescue experiments with PEP Prx2 corroborate the pivotal role of Prx2 in lung homeostasis.

The behavior of defensive autophagy in Prx2−/− mice exposed to...
hypoxia is strongly linked to ER stress in the absence of Prx2. Treatment with PEP Prx2 reduced ER stress and switched-off autophagy as supported by the reduction in LC3II and accumulation of p62 (Fig. 6A). This was parallel by a decrease of hypoxia induced HSP70 and 90 expression and down-regulation of GADD34 and ATF6 levels in PEP Prx2 treated Prx2-/- mice exposed respectively to 3 and 7 days hypoxia.

Collectively, our data indicate that PEP Prx2 has a multimodal action targeting: (i) the inflammatory response; (ii) vascular and extracellular matrix remodeling, (iii) ER stress and autophagy (Fig. 7B). The correction of the imbalance between oxidation and anti-oxidant systems combined with a chaperone like function exerted by Prx2 might interrupt the vicious circle, established between oxidation-chronic inflammation with ER stress and activation of autophagy towards the generation of PAH (Fig. 7B).

In conclusion, we have firstly highlighted the novel pivotal role of Prx2 in preventing PAH induced by hypoxia. The high bio-complexity of PAH requires multimodal therapeutic approaches, which simultaneously act on different targets involved in its pathogenesis. Our data collectively support a rationale for considering Prx2 as novel therapeutic option in treatment of the early phase of PAH.

Authorship and contributions

EF, AM, LDF, IA, DM designed the experiments, analyzed data and wrote the paper; AJ, CL carried out the histologic analysis; AM, AS, LDF carried out the experiments; IA performed the molecular experiments and analyzed the data; CSY and KDW generated the PEP Prx2; SL carried out MDA measurements and analyzed data.

Diagram of the novel role of Prx2 in pathogenesis of PAH induced by hypoxia and the novel multimodal action of Prx2 against hypoxia induce cytotoxic effects. Hypoxia promotes oxidation and induces acute phase inflammatory response, which is related to the activation of Nrf2, NF-kB. In the meantime, the accumulation of damage of cellular organelles and proteins results in activation of UPR system to limit endoplasmic reticulum (ER) stress, associated with increased expression of classical chaperones such as heat shock protein 70 and 90, and Prx2. ER stress leads to activation of autophagy as secondary mechanism to degraded damage proteins and reduce ER stress. This is supported by (i) conversion of LC3II to LC3I, and (ii) clearance of p62 positive lysosomes combined with the activation of caspase 3 pathway. PEP Prx2 treatment (i) prevents the hypoxia induced acute phase response activation of transcriptional factors NF-kB and Nrf2, (ii) alleviates ER stress related to hypoxia with reduction of ATF6 levels and (iii) blocks hypoxia induced autophagy. This results in reduction in markers of vascular remodeling, of extracellular matrix deposition and the abnormalities in pulmonary vascular leakage.
